# Complex Metal Hydrides

Overview

★ Introduction

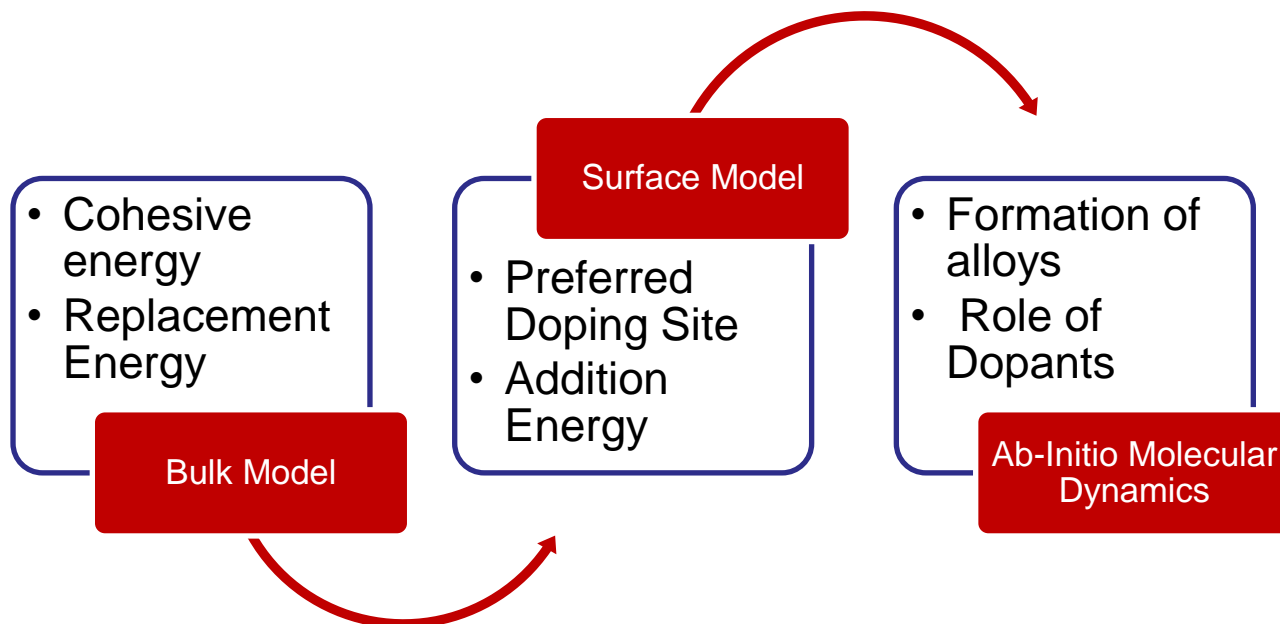

Methods

Results

Conclusions

Acknowledgements

- **Goal** : Improve ability to design materials for hydrogen storage/explore wide range of promising hydrogen storage systems
- **Method** : First-principles investigation of effect of catalytic additives in structural dynamics of bulk and surface models in Complex Metal Hydrides (CMHs)

# Hydrogen Storage

## CMHs currently under study:

### Decomposition of NaMgH<sub>3</sub>

\*6 % wt. hydrogen capacity

### Research Opportunity

- **Higher H mobility** in this material due to their perovskite structure cause improved hydrogenation rates compared to pure MgH<sub>2</sub>
- These structures may enhance kinetics and reversibility and inhibit toxic gas side products compared to borohydride, amide, and alanate compounds

# NaMgH<sub>3</sub>

Overview

★ Introduction

Methods

Results

Conclusions

Acknowledgements

- **Complex Metal Hydrides** have attracted interest, experimental findings show that decomposition temperature for CMHs can be modified by introduction of additives

NaMgH<sub>3</sub> Unit Cell

- **Structure and Dynamics**  
Overall goal of First Principles calculations for 3d/4d-Transition Metal **Doping** is to determine:

- Structural stability
- Preferred doping site
- Cohesive energy

2x1x2 Supercell

# Modeling Approach

Overview

Introduction

Results

Conclusions

Acknowledgements

- First principles calculations done with Density Functional Theory (DFT)
  - Generalized gradient approximation (GGA)
    - PW91 for Geometry Optimization
    - PBE for Single-Point Energy Calculations
  - All the simulations successfully completed are performed using the plane wave pseudo-potential implementation of DFT as applied in the CASTEP® module of the Materials Studio® suite from Accelrys
  - DFT coupled MD is used to study the behavior of the system in canonical and microcanonical ensembles at high temperatures (423 K & 448 K)
    - NVT and NVE Ensembles
    - Gamma K-pt sampling

## Cohesive Energies for Models

- Energy of free neutral atoms is calculated by placing an atom in a  $10\text{\AA} \times 10\text{\AA} \times 10\text{\AA}$  box with gamma Kpt set and  $E_{\text{cutoff}} = 400 \text{ eV}$
- Energy of atoms with unpaired electrons is obtained through spin-polarized simulations
- $E_{\text{add/sub}} = (E_{\text{Doped system}} - E_{\text{pristine system}})/N$
- $E_{\text{cohesive}} = E_{\text{total system}} - \sum E_{\text{free neutral atoms}}$

Titanium atom placed in a  $10\text{\AA} \times 10\text{\AA} \times 10\text{\AA}$  box

## Structural and Electronic Properties of Pure Crystal Structure

### ➤ Ground State Structure

- Geometry optimization performed for the orthorhombic structure using (PW91/USPP/400 eV)
- Convergence check with respect to kinetic energy cutoff and k-point mesh
- Lattice parameters, bond lengths and angles in agreement with experimental results.  $\Delta$  Volume = <0.20%

$\text{NaMgH}_3$  Optimized Cell, consisting of 2 f. u.

Lattice Constant	Lattice Parameter (Å) Experimental	DFT-PW91 Results
a	5.463	5.48
b	7.703	7.68
c	5.411	5.40

# Pure Crystal Structure

## Structural and Electronic Properties of Pure Crystal Structure

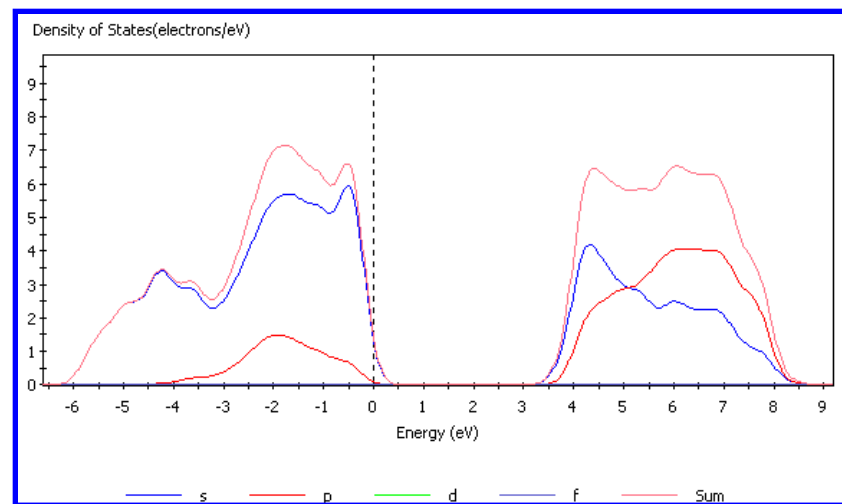

### ➤ Electronic Properties

- Insulator with energy gap of 3.35 eV. Similar to values found in literature (3.3-3.5 eV)

### ➤ Electronic Properties

- Partial Density of States (PDOS) shows Interaction between Na and MgH<sub>3</sub> is ionic and that between Mg and H comprises both ionic and covalent character.

# Bulk Model Results for 3d Transition Metals

Overview

Introduction

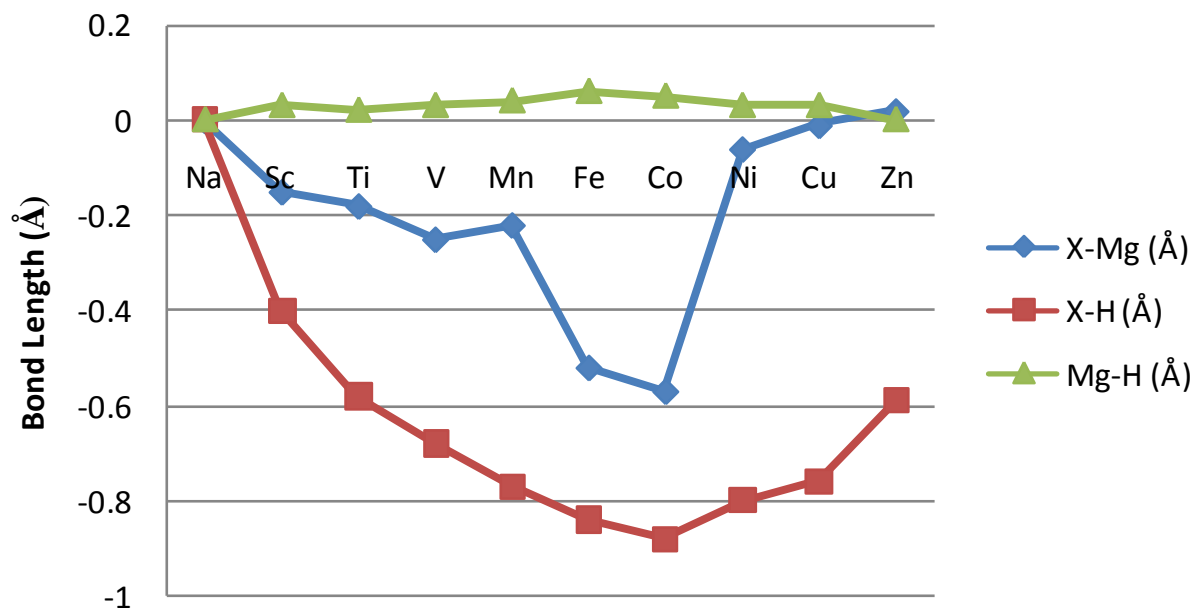

Methods

★ Results

Conclusions

Acknowledgements

## Trends in Bond Length ( $\text{\AA}$ )

- Where X : Na, Sc, Ti, V, Mn, Fe, etc
- Elongation and possible weakening of Mg-H bond when Ti, V, Mn, Fe, and Co substitutes Na at Na site

# Bulk Model Results for 3d Transition Metals (continued)

Overview

Introduction

Methods

Conclusions

Acknowledgements

## Trend in Cohesive Energy (eV)

$$\text{➤ } E_{\text{cohesive}} = E_{\text{total system}} - \sum E_{\text{free neutral atoms}}$$

➤ \*Cohesive Energy is calculated relative to the pure model

➤ The higher the cohesive energy in crystalline element, the higher the energy in bulk model.

# Bulk Model Results for 3d Transition Metals (continued)

Overview

Introduction

Methods

★ Results

Conclusions

Acknowledgements

### Trends in Ionization Energy (eV)

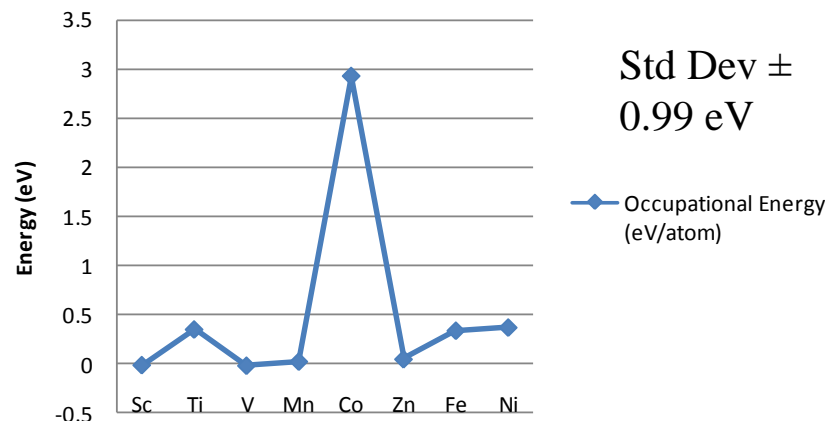

➤ Transition elements with higher ionization potential (RHS) lowers cohesive energy of system, leading to destabilization of the bulk model

➤ Elements in LHS show increased association with Mg and H

➤ Ti and Zn for further study, representing LHS and RHS of periodic table

$$\text{➤ } E_{\text{add/sub}} = (E_{\text{Doped system}} - E_{\text{pristine system}})/N$$

### Occupational Energy (eV/atom)

# Bulk Dehydrogenation Energy Comparison ( Ti/Zn)

Overview

Introduction

Methods

★ Results

Conclusions

Acknowledgements

Model	Dehydrogenation Energy (eV)/H <sub>2</sub>
Pure	0.00*
Zn-doped	-1.31*
Ti-doped	-1.38.

\*Energy relative to Pure Model

$$\Delta E = E(\text{X})\text{Na}_{15}\text{Mg}_{16}\text{H}_{48} - (E(\text{X})\text{Na}_{15}\text{Mg}_{16} + 24E\text{H}_2)$$

# Surface Density Difference Map (Ti-doped)

Introduction

Methods

★ Results

Conclusions

Acknowledgements

( View parallel to x and y axis)

(Side View)

➤ Loss of electrons is indicated in blue, while regions rich in electrons are indicated in red. White colors indicate regions with small changes in the electron density

# Surface Density Difference Map (Ti-doped)

Overview

Introduction

Methods

★ Results

Conclusions

Acknowledgements

(Top View)

(Side View)

- Blue region in Ti-doped model is more intense.
- Signaling greater depletion of electrons to surroundings

# Bulk Model Results for 4d Transition Metals

Overview

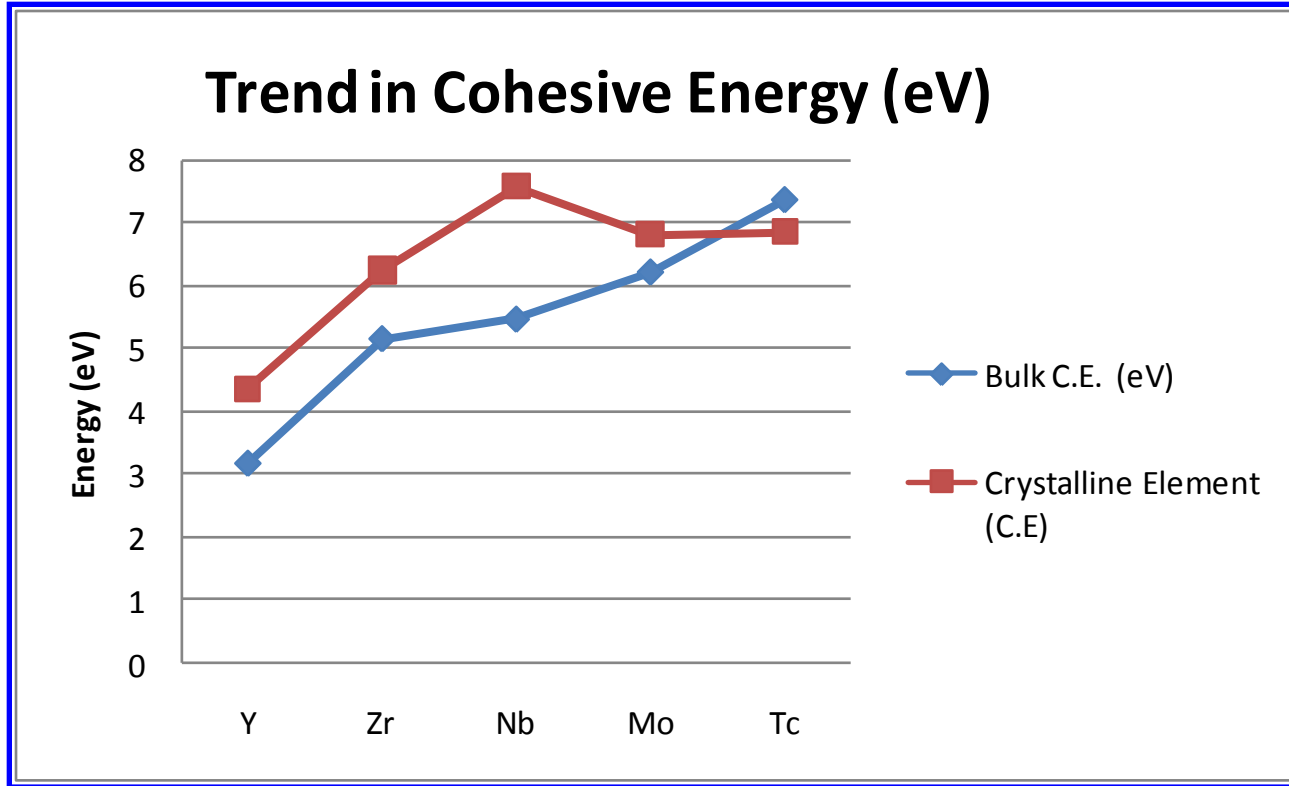

Introduction

Methods

★ Results

Conclusions

Acknowledgements

- For the 4d block, all the models show a high positive cohesive energy with respect to the pure model
- Models are stable, formation of alloys is possible
- Tc has a C.E. 2.5 times greater than Ti

# (001) Surface Energy

Site	System	$E_{\text{coh}}$ (eV)	$\Delta E_{\text{add}}$ (eV/ atom)
Ti@ Na site	TiNa <sub>7</sub> Mg <sub>8</sub> H <sub>24</sub>	4.60	-
Ti @ Hollow Site	TiNa <sub>8</sub> Mg <sub>8</sub> H <sub>24</sub>	5.47	0.13
Ti@ Top Na site	TiNa <sub>8</sub> Mg <sub>8</sub> H <sub>24</sub>	3.22	0.08
Ti@ Top Hollow Site	TiNa <sub>8</sub> Mg <sub>8</sub> H <sub>24</sub>	3.22	0.08
Ti@ Mg Site	TiNa <sub>8</sub> Mg <sub>7</sub> H <sub>24</sub>	4.23	0.11
H removed from Ti@ Na site	TiNa <sub>7</sub> Mg <sub>8</sub> H <sub>23</sub>	3.05	-
H removed from Pure model	Na <sub>8</sub> Mg <sub>8</sub> H <sub>23</sub>	-3.46	-

- \*\* Cohesive energy is relative to pure model
- **Most favorable models : Ti @ Na site and Ti @ Hollow site**
- Ti@ Top Hollow site and Ti @ Top Na site have same cohesive energy
- Ti@ Mg site is more favorable than Top Hollow and Top Na site
- More favorable to remove hydrogen from Doped model

## DFT-MD @ Interstitial Site

## DFT-MD @ Na Site

# Conclusion

Overview

Introduction

Methods

Results

★ Conclusions

Acknowledgements

- Cohesive Energy may be useful physical quantity for evaluating hydrogen desorption ability
- High Ionization energy of RHS dopants is responsible for thermal stability
- Site preference of dopants determined by cohesive energy, atomic size and ionization energy
- Ti-Mg<sub>x</sub>H<sub>x</sub> complexes are observed after geometry optimization of doped-surface models
- DFT coupled MD simulations show the existence of Ti-Mg<sub>x</sub>H<sub>x</sub>,
- Substitution and addition energy of surface models show that Ti @ Hollow site and Ti @ Na lattice site have almost equal energies
- Ti-doping helps increase hydrogen mobility (hopping)
- Hydrogen mobility is not rate-limiting process in this system

# Future Work : Synergistic Effect of TMs as Co-Dopants
